Received February 12, 2010

Background & objectives: The greater tendency to diabetes in Indians may be due to genetic factors in addition to environment and diet. *CD36*, a class B scavenger cell surface receptor mediates internalization of oxidized low density lipoprotein (Ox-LDL) leading to the formation of macrophage foam cells. *CD36* deficiency is related to phenotypic expression of the metabolic syndrome, frequently associated with atherosclerotic cardiovascular diseases resulting in raised levels of glucose thereby contributing to type 2 diabetes (T2DM). Therefore, the association of human *CD36* gene mutation to T2DM needs investigation.

We undertook this study to investigate *CD36* gene status in north Indian subjects by screening for the deletion of exons 3, 4 and 5 and certain polymorphisms.

Methods: Clinical characteristics were compared between 300 T2DM patients and 100 healthy controls. Deletion analysis was carried out for exons 3, 4 and 5 of *CD36* gene in 300 T2DM patients using PCR and agarose gel electrophoresis. Genotype analysis for two polymorphisms 478C>T and delAC in exons 4 and 5 respectively was carried out using PCR-RFLP method.

Results: Biochemical parameters such as fasting and post-prandial glucose levels, total cholesterol, LDL-cholesterol and blood pressure were slightly raised in the T2DM patients when compared with controls with lowered HDL-cholesterol. No exonic deletion was observed in the 300 patients and 100 controls screened. All individuals were found to be homozygous (CC and -/-) for the two polymorphisms studied.

Interpretation & conclusions: Although no exonic deletion was found in T2DM patients, our study suggests that all 15 exons need to be screened for mutations which lead to *CD36* deficiency. Genotyping studies of the two SNPs in the *CD36* gene confirmed the absence of exons 4 and 5 deletion. This is perhaps the first report from India suggesting that *CD36* is one of the several important genes that need to be explored in relation to T2DM.

Key words Biochemical characteristics - *CD36* gene - deletion - exons - type 2 diabetes

Type 2 diabetes mellitus (T2DM) is the common form of diabetes accounting for 90 per cent of cases worldwide and is continuously increasing. Over the past 30 years, the status of diabetes has changed from being considered as a mild disorder of the old age to one of the major causes of morbidity and mortality affecting
the young and middle aged people. It is estimated that approximately 285 million people worldwide, or 6.6 per cent in the age group 20-79 yr, will have diabetes by the end of 2010, 70 per cent of whom live in low- and middle-income countries. This number is expected to increase by more than 50 per cent in the next 20 years if preventive programmes are not put in place. Some 438 million people, or 7.8 per cent of the adult population, are projected to have diabetes by 2030. The largest increases will take place in the regions dominated by developing economies as is evident from the alarming number of diabetic patients in India1,2.

T2DM occurs primarily due to a ‘high blood sugar level’ resulting in hyperglycaemia, glycosuria, dyslipidaemia, high levels of low density lipoproteins (LDL) and low levels of high density lipoproteins (HDL). If remained uncontrolled, T2DM may lead to various complications such as abdominal obesity, hypertension, atherosclerosis, stroke, coronary heart disease, etc. However, the mechanisms involved in determination of the risk of developing diabetes are still not known clearly. It has been established that T2DM has a genetic component and several candidate genes are responsible for inducing susceptibility to this disease such as adiponectin gene (ADIPOQ), TCF7L2, β3 adrenergic receptor (β3AR) gene and many more3-8. There have been reports of a gene coding for a macrophage receptor, CD36 which has shown association with hypertension and metabolic syndrome in the Caucasian and African-American populations, respectively9,10.

CD36 is a 88 kDa integral transmembrane protein, one of the most important molecules found on the surface of many cells in vertebrates and has the ability to endocytose oxidized LDL (OxLDL)11,12. Several studies suggested the role of CD36 as an important regulator of the metabolic pathways involved in insulin resistance13-15. The pathophysiology of human CD36 deficiency in metabolic syndrome and atherogenesis has been explained16. Highly oxidized lipoproteins can be rapidly taken up by macrophages to give rise to foam cells, cholesterol engorged cells that are hallmark of early atherosclerotic lesions. The increased fatty acid availability can induce insulin resistance if the capacity of adipose tissue to store triglycerides and/or that of muscle to oxidize FA is exceeded17. A recent report has shown that alteration in CD36 levels might be involved in the development of diet-induced insulin-resistance in mice18.

CD36 gene has 15 exons extending over 32 kb on chromosome 7q11.219,20. It has been reported that genetic factors like single nucleotide polymorphisms (SNPs) in the CD36 gene are significantly associated with T2DM10,21-23 while exonic deletions such as exons 4, 9, 11, 12 and 13 in the CD36 gene lead to its deficiency24-26. Deletion of exons 3, 4 and 5 in CD36 gene has been studied in the Japanese population24 while significant alteration in the activity of CD36 gene has been shown to occur due to small nucleotide deletions of 10, 12, 16 and 29 bps27,25. Exon 3 contains the last 89 nucleotides of the 5′-untranslated region, encodes the N-terminal cytoplasmic and transmembrane domains. Deletion of the two non-coding exons 1 and 2 along with third exon results in no expression of CD36 protein. Exons 4 and 5 encode amino acids 41-94 and 94-143, respectively which constitute potential N-glycosylation sites. The skipping of these exons results in a defect of the ligand binding site of CD36 protein28.

CD36 deficiency can be divided into two subgroups, type I in which neither platelets nor monocytes/macrophages express CD36, and in type II monocytes/macrophages express CD36 but platelets do not. Two important mutations in CD36 gene responsible for CD36 deficiency are SNP T/C at nt 478 of CD36 (Exon 4) and a dinucleotide deletion (delAC in Exon 5)27-29. The 478C>T polymorphism (proline-90 serine) predominates in the type I and type II CD36 deficiency24,28 via defects in post-translational modification, while the dinucleotide deletion causes a frameshift mutation leading to the appearance of a translation stop codon and a marked reduction in the level of CD36 mRNA.

The role of CD36 gene in lipid metabolism and T2DM susceptibility prompted us to take up this study on CD36 gene status in the north Indian population. We screened the deletion of exons 3, 4 and 5 and the polymorphisms viz. 478C>T SNP in exon 4 and a delAC in exon 5 of the CD36 gene.

**Material & Methods**

**Sample collection:** The study protocol was approved by the institutional ethical committee of Chatrapati Sahuji Maharaj Medical University (CSMMU), Lucknow, and the study was performed during March-November, 2009. Written informed consent was obtained from all participants. Blood samples were collected randomly from 300 patients (173 males and 127 females) from the Diabetic Clinic of Medicine OPD, CSMMU, Lucknow and their clinical details, family history of
diabetes and associated complications were recorded. Control samples (n=100) were collected from healthy staff members and students of University of Lucknow. The screening and management of patients were done as per American Diabetes Association guidelines\textsuperscript{30}. Criteria for patients’ participation included fasting plasma glucose (FPG) $\geq 126$ mg/dl or a 2 h blood glucose level of $\geq 200$ mg/dl after a 75 g oral glucose load (oral glucose tolerance test). Individuals with a history of major illness were excluded. Normal individuals were included on the basis of normal FPG of 70-109 mg/dl or random plasma glucose (RPG) 110-199 mg/dl.

**Biochemical parameters:** Two ml blood samples were equally distributed in two vials, one ml in 0.5M EDTA and the other in a plain vial for DNA extraction and biochemical estimations respectively. Serum was collected from the blood in plain vials after centrifugation for 10 min at 2655 g at 4°C. Estimations of plasma glucose (mg/dl), serum insulin (mg/dl) and lipid profile (total serum cholesterol, TC; High density lipoprotein-cholesterol, HDL-C and serum triglycerides, TG) were done using commercially available \textcopyright{}Ecole kits (Merck, India) by double beam spectrophotometer (Shimadzu, Japan) at 550 nm (TGL-C), 510 nm (S. creatinine), 500 nm (TC) and 560 nm (HDLC). Height, weight and waist circumference were measured to calculate body mass index (BMI) and waist hip ratio (WHR). Systolic and diastolic (disappearance of Korotkoff sound, phase V) blood pressures were measured in the sitting position with an appropriately sized cuff after a 5 min rest. Clinical details of patients and control subjects were recorded (Table I).

**DNA extraction and deletion analysis:** DNA was extracted from blood samples of T2DM patients using the salting out method\textsuperscript{31} with slight modifications. Lysis was followed by protease K buffer (0.375M NaCl, 0.012M EDTA) and SDS (10%) treatment. After frothing, cold 5M NaCl was added followed by phenol-chloroform extraction. DNA was checked on 0.8-1 per cent agarose gel. The quantity of DNA was estimated using double beam UV-visible spectrophotometer and quality was checked by measuring $A_{260}/A_{280}$: Exons 3 (nt 1722 to 1986), 4 (nt 12038 to 12404) and 5 (nt 17779 to 17977) of CD36 gene were amplified by polymerase chain reaction (PCR) using respective primers using Master Cycler ep Gradient (Eppendorf, Germany)\textsuperscript{24}. The primer sequences and PCR conditions are shown in Table II. PCR was performed for 30 cycles using 0.5U Taq polymerase, 10 pmol/µl of each primer, and 200µM dNTP in 25µl reaction volume. The PCR products were checked on 1.5 per cent agarose gel along with 50 and 100 bp markers. The gels were documented and analyzed.

**Genotype analysis:** Two polymorphisms in CD36 gene responsible for exon deletions \textit{viz.} 478C>T and a dinucleotide deletion (delAC) in exon 5 were analyzed in T2DM patients and control subjects by polymerase chain reaction and restriction fragment length polymorphisms (PCR-RFLP)\textsuperscript{24,27-29}. The primers used were as shown in Table II and the restriction enzymes used were \textit{Cfr131} and BoxI, identified by NEB cutter software (www.tools.neb.com/NEB cutter 2) for 478C>T and delAC respectively. The PCR amplicons and digested products were resolved on 10 per cent polyacrylamide gels (PAGE), stained with ethidium bromide and documented in Gel Doc (Vilber Lourmat, France).

**Statistical analysis:** Statistical analysis was applied to biochemical data using SPSS software (www.spss.com) (v15.0). Mean ± SD (standard deviation) of all clinical parameters and diabetic duration was calculated in each age group ($\leq 40$, 41-59 and $\geq 60$ yr) as well as in BMI groups ($<18.5$; $18.5-25$ and $>25$ kg/m$^2$). $P$ values were calculated by 2x2 contingency table using paired t-test. All $P$ values were two sided and $P<0.05$, was considered significant.

**Results & Discussion**

The average age of the patients was $48.61\pm9.96$ yr and their fasting and post-prandial glucose levels were

| Table I. Clinical parameters of T2DM patients and control subjects |
|--------------------------|--------------------------|
| **Clinical parameters**   | **Controls (n=100)**     | **Patients (n=300)**    |
| Age (yr)                  | 42.88 ± 9.75             | 48.61 ± 9.96            |
| BMI (kg/m$^2$)            | 23.40 ± 1.89             | 23.95 ± 4.46            |
| WHR (Waist hip ratio)     | 0.93 ± 0.06              | 0.95 ± 0.54             |
| Fasting plasma glucose (mg/dl) | 92.63 ± 15.28          | 165.40 ± 69.65          |
| Post-prandial plasma glucose (mg/dl) | 160.30 ± 24.67       | 266.40 ± 97.04          |
| Total cholesterol (mg/dl) | 157.70 ± 40.47           | 233.98 ± 26.13          |
| Triglyceride (mg/dl)      | 136.30 ± 66.85           | 116.75 ± 15.31          |
| HDL-cholesterol (mg/dl)   | 61.93 ± 12.25            | 42.21 ± 4.19            |
| LDL-cholesterol (mg/dl)   | 68.52 ± 43.51            | 168.61 ± 26.13          |
| VLDL-cholesterol (mg/dl)  | 27.25 ± 13.37            | 23.34 ± 3.16            |
| Serum creatinine (mg/dl)  | 1.08 ± 0.03              | 1.05 ± 0.10             |
| Blood pressure systolic (mmHg) | 117.32 ± 3.99        | 135.22 ± 19.35          |
| Blood pressure diastolic (mmHg) | 77.36 ± 4.93           | 84.27 ± 10.77           |

Values are expressed as mean ± SD.
165.40 ± 69.65 and 266.40 ± 97.04 mg/dl, respectively. The average systolic BP was slightly elevated (135.22 ± 19.35 mmHg) and the mean diastolic pressure was almost normal (84.27 ± 10.77 mmHg). Total cholesterol (233.98 ± 26.13 mm/dl) and LDL-C (168.61 ± 26.13 mmHg) levels were slightly raised and HDL-C was low (42.21 ± 4.19 mmHg). However, no significant difference was observed in BMI, WHR, triglycerides and serum creatinine levels between the T2DM and control groups (Table I).

The PCR products of exons 3 (265 bp), 4 (358 bp) and 5 (199 bp) are shown in Fig. 1. Exonic deletion was observed neither in patients nor controls. In our study population all individuals (patients and controls) were found to be homozygous ‘CC’ and -/- for 478C>T and delAC polymorphisms respectively (Fig. 2).

CD36, being an important receptor molecule for modified lipoproteins, plays an important role in the regulation of lipid metabolism. Studies have shown its involvement in diverse disorders such as insulin resistance, dyslipidaemia, hyperlipidaemia, atherosclerosis32,33 and T2DM21,-22. Lipid abnormalities in CD36 deficiency might depend on the presence of diabetes since the total cholesterol and triglyceride levels in diabetic CD36 deficient patients were higher than in control subjects and non-diabetic CD36-deficient patients33. Several kinds of CD36 gene mutations have been reported in CD36-deficient patients25. A dinucleotide (AC) deletion in exon 5 of CD36 gene led to a frameshift mutation resulting in a stop codon24 while the insertion of nucleotide A at position 1159 led to the abnormal splicing in mRNA resulting in skipping of exons 4, 9, 11 in type 1 CD36 deficient subjects26. However, our study did not show deletion of exons 3, 4 and 5 of the CD36 gene in north Indian T2DM patients as well as controls. All individuals tested for

**Fig. 1.** Agarose gels showing PCR products of (A) Exon 3, (B) Exon 4, (C) Exon 5, Lane M:100 and 50 bp ladder.

**Fig. 2.** (A). Gel showing 478C>T SNP in exon 4, lane M, 50 bp ladder; lane UD, undigested PCR product; lanes 1-4, 5-8, PCR products digested with Cfr131 showing CC genotype. (B). Gel picture of delAC in exon 5, lane M, 50 bp ladder; lane UD undigested PCR product; lanes 1-3, 4, 5-8, Box I digested PCR products showing -/- genotype.
478C>T and delAC polymorphisms were ‘CC’ and ‘-/-’ homozygotes respectively. This suggests that in our population CD36 exonic deletion is not prevalent; as a result deficiency of CD36 protein is not evident.

CD36 expression in monocytes is upregulated by oxidized low density lipoprotein (Ox-LDL), whose levels increase in case of T2DM, hyperglycaemia and related atherosclerosis15. CD36 deficiency can promote defective insulin action (resistance) and disordered fatty acid metabolism in spontaneous hypertension34.

Although the molecular aspects of CD36 and its complications are not very clear, there have been attempts to study its polymorphisms and their association with T2DM. CD36 genotype was identified as a fundamental determinant of myocardial long chain fatty-acid uptake13,35,36. We have recently reported that one of the several SNPs in the CD36 gene (rs1761667, G>A) shows a significant association with T2DM in one of the several SNPs in the CD36 promoter -178 A/C SNP promoter and other populations such as the -178 A/C SNP promoter of the CD36 gene in the French population21,22.

Our findings are in support of the data obtained from the technicians at the Diabetes Clinic, CSMMU, Lucknow. Fellowship, RGNF, UGC, New Delhi.
